ABSTRACT

Thailand has currently enhanced and promoted intensive trade and investment liberalisation and implemented long-term growth policy according with current regional economic integration, WTO obligations and globalisation. Nevertheless, several recent internal and external factors e.g. the massive SARS and avian flu outbreaks, the Indian Ocean tsunami devastation, the Asia financial crisis and domestic policy reforms (ICSEAD, 2006) have also impeded this policy. While the issues are important for Thailand and developing countries in Asia, only limited research has been undertaken to investigate them. The paper conducts a substantive quantitative study to contribute to these trade and development policy issues. A new econometric modelling policy method, namely the generalised gravity theory (Tran Van Hoa, 2004) is used to develop a simple flexible simultaneous-equation econometric model of Thailand’s openness model with its seven major trade partners (ASEAN-4, Australia, the USA, the EU, China, Japan and India). Using data from the ICSEAD, the World Development Indicators and the Bank of Thailand databases, the paper reveals efficient and reliable empirical findings on trade-growth causality, trade determination including the impact of shocks and policy reform on trade and growth between Thailand and its major trade partners over the past two decades. The paper also provides evidence on the linkages between trade in goods, FDI and services and regional economic integration for more credible policy implications. The implications for Thailand’s openness policy in terms of opportunities and challenges under the context of multilateral, regional and bilateral free trade agreements are also discussed.

Keywords: Thailand Trade and Investment Liberalisation, Regional Economic Integration, Free Trade Agreements, Trade and Growth Causality, Generalised Gravity Theory, Modelling Economic and Trade Policy.

1. INTRODUCTION

Asian developing economies have recently intensive implemented trade liberalisation policies to promote growth under the multilateral, regional and unilateral frameworks. Thailand is one of these economies achieving miracle in the past two decades. Nevertheless, many challenges consisting of the global economic recession, the Asian financial crisis as well as the SARS and avian flu outbreaks and the Indian Ocean tsunami affect the economy performance of Asia developing economies including Thailand. The development and growth perspective for Thailand in response to and consequences of these internal and external shocks combining with structural or policy reform particularly Thailand’s trade and economic relations or co-operations in medium and long term is interested to examine.
The paper undertakes an empirical study utilising trade-growth time series modelling analysis. The plausible policy implications and recommendations are also proposed. This paper is time series quantitative and policy-based study. It contains many important features. Firstly, it reviews current trade liberalisations in the context of multilateral, regional and unilateral frameworks as well as regional economic integration and closer economic relations of Thailand and in the Asian region. Secondly, it proposes and formulates the concept of trade-growth by constructing a plausible and flexible the simultaneous-equation econometric model of trade and growth and trade between Thailand and its seven major trading countries and blocs namely the ASEAN-4, Australia, China, the EU, Japan, India and the USA. Thirdly, the model incorporates the crisis and shocks and policy reforms affect the growth of Thailand. Fourthly, the recent ICSEAD, World Bank and IMF data is used to estimate the model. Finally, according to the reliable causality results on trade-growth and the impact of structural changes and shocks on the economy of Thailand in the past two decades. As a result, the discussion of economic and trade policy implications based on the findings are aimed to include in the paper.

2. THAILAND’S RECENT ECONOMIC AND TRADE DEVELOPMENT

This section reviews Thailand’s recent economic and trade developments. The GDP increased gradually from 2,941.74 billion of baths in 1995 to 3,072.61 billions of bath in 1997. However, the GDP decreased significantly to 2,871.98 billions of bath in 1999 due to the Asia economic crisis. The international reserve decreased sharply from 46.5 billions of US dollars in 1995 to 23.1 billions of US dollars in 1997 because of the intensive currency attack beyond the Asia financial crisis. Nevertheless, the international reserve continually increased from 34.8 billions of US dollars to 52.1 billions of US dollars due to the increased balance of payment and the recovery economy between 1999 and 2005. The huge slow down of the exports resulting in the current account balance deficit was about 13.2 billions of US dollars in 1995. The current account deficit decreased to about 3.1 billions of US dollars and then significantly increased to more surpluses to 11.3 billion of dollars in 1999. On the contrary, there was a current account deficit of 3.7 billions of US dollars again in 2005. The balance of trade was fluctuated between 1999 and 2005 from surplus of 8.9 billions of US dollars to deficit of 8.6 billions of US dollars. The balance of payment was surplus of 7.2 billions of US dollars in 1995. There was a considerably balance of payment deficit of 10.6 billions of dollar in 1997. The balance of payment was obviously fluctuated from surplus of 4.6 billions of US dollars in 1999 to surplus of 5.4 billions of US dollars in 2005.

The inflation rate decreased slightly from 5.8 % in 1995 to 5.65% in 1997. The inflation rate fluctuated gradually to 0.2% and 1.6% in 2003 and 2005 respectively. In contrast, total debt outstanding increased significantly from 100,039 millions of US dollars in 1995 to 109,276 millions of US dollars in 1997 due to the Asia financial crisis and bath devaluation. However, the total debt continually decreased to 52,040 millions of US dollars in 2005 because of the payment of the IMF loan. The average exchange rate was 24.9 bath per US dollar and depreciated to 31.2 bath per US dollar due to the Asia financial crisis and the manage float system. There was peak depreciation to 45 baht per US dollar in 1999. In 2005, the bath was appreciated to 40.3 baht per US dollar. There was 3.8% of unemployment rate in 1995 and increased considerably to 5% in 1997.

In terms of the trend of Thailand’s tariffs, there are downwards in regarding the trend of Thailand’s tariffs. However, the tariff rates have less fluctuated since December 1994 due
to the membership of the WTO. There are many reasons to explain the motivation of the WTO membership for Thailand consisting of improving and harmonizing the tariff system, improving and expanding market access in the potential member countries (WTO, 2000). As a result, since 1995 the Thai government has implemented several obligations of the WTO to reduce and eliminate the market access barriers. However, there are a few quantitative restrictions exists in the agriculture, textile and clothing sectors. Thailand has achieved many successes in trade policy reform to promote trade and the economic cooperation due to the WTO membership, such as the tariff and non-tariff barriers elimination negotiation, regional trade liberalization and harmonization in the issues of standards and regulations.

The development of Thailand’s trade policy is combined with many transformations. It can be explained clearly when the national economic and social development plan is set up and implemented. From 1960s and 1970s, the import substitution policy was adopted to accelerate industrialisation. Many schemes were used to reach this goal, such as the establishing of industrial processing zone in the eastern region to promote industries utilising domestic raw materials. Since 1980s, trade policy has been shifted to export promotion policy because of the economic recession and intense competition environment. Several regimes have been implemented to enhance growth and increase export competitiveness. The industries produce over domestic demand goods has motivated to invest in industrial processing zone for export markets. The export and import bank has been set up to support, facilitate and finance the import and export entrepreneurs.

From late 1980s to 2000s, the export promotion policy was still the dominant. This policy was adapted more intensively to solving the balance of payment crisis leading to the Asia financial crisis in 1997. The industrialisation structure adjustment was implemented to support high quality goods including processed agricultural and manufactured goods. The labour skill development institution was established to increase the skills of labour supporting this policy. The severe competition and the increasing of trade blocs influence the implementation of the FTAs regime. As a result, the regional and bilateral FTAs were the important policy commenced in 2001 to expand high potential markets and increase trade partners.

Presently, it can be said that Thailand has the most ambitious in the region due to its intensive efforts to increase its world export market share through the establishing of both regional and bilateral free trade agreement (Tulyanond, 2005). Free trade agreement with India encompasses only 83 products while with Australia consists of more than 5,500 items. This agreement became effective on January 2005. The deadline of tariffs reduction of different products is different in both countries. Thus, free trade agreement with Australia is the most comprehensive agreement. The key of the success is the achievement of the extensive market access that each country will afford via intensive tariff reductions. On the other hand, free trade agreements with New Zealand, the United States and Japan are under the negotiating processes. The agreement structure with New Zealand is resembled to the conclusion of Thailand-Australia FTA. The agreement with the U.S. confronts with many difficulties because it relates with non-trade related issues. These issues consist of corruption, competition policy and government procurement that impede the negotiation process.
3. THE CRISES, SHOCKS AND POLICY REFORMS IN THAILAND

The apparently most serve external shock in the region is the Asia financial crisis commenced in Thailand in July 1997. This crisis spread widely and has domino affect on the economy performance of the region. During the late 1980s until the early 1990s, Thailand has liberalised its capital account flow by less restrict and removed barriers on the inflow and outflow of capital via the implementation of the Bangkok International Banking Facility scheme (Phongpaichit and Baker, 2000). The massive amount funds flow into the economy. Thai commercial banks including firms borrow huge fund from external sources due to the high different interest rates. These foreign funds are invested mainly in the stock market to seeking the benefits from high return. This is the main factor to drive Thailand known as one of the emerging market.

Moreover, the commercial banks and financial firms misuse the foreign short-term borrowings by lending to long-term unproductive projects e.g. real estates. In addition, the credit allocation of these financial institutions is undertaken and determined under insufficient prudential risk assessment resulting in the surged increase in outstanding non-performance loans (NPLs). In May 1999, NPLs of total commercial bank credits reached 47.7 per cent (Phongpaichit and Baker, op. cit., 2000). The economic expansion is distorted because of the commercial banks and other financial institutions are unable to inject more credit to the economy. The Thai baht is also attack and speculate intensively simultaneously due to the currency overvaluation.

According to the unprecedented capital outflow combining with trade deficit, the unexpected twin balance of payment deficit, trade and capital account deficit. Besides that, the total outstanding foreign debt of both government and private sector jump up bloody. The Bank of Thailand loses massive international reserves intervening the exchange market to protect the baht attack and speculation. Therefore, it is unavoidable for Thailand to abandon the fixed exchange rate regime and adopt the managed float system. When the financial crisis approaches, Thai economy turns to recession after serval years of economic boom. Several export industries detract and become uncompetitive leading to the huge decrease in export shares and earnings. The high foreign indebted finance companies and commercial banks become insolvency and bankrupt.

The financial institution and system play vital role in enhance the economy performance. This factors are fragile and inefficiency in most of developing economies. During the last decade, apparently dominant domestic reforms are financial sector reforms. The financial reforms have been implemented mainly by the urgent needs of crisis resolution and force the economy back to normal performance situation. High growth and emerging economy of Thailand is driven by the high growth of financial sector (Menkhoff and Suwanaporn, 2007). However, the fragile, unwell planned development and inappropriate functioning of financial sector accelerate the attack of financial crisis began in July 1997. The intensive financial system reforms have undertaken during the last five years.

From the above, it can be said that the crises, shocks and policy reform have significant impact on trade and growth for a small developing economy like Thailand. These obstacles can distort the expected benefits from trade liberalisation and economic cooperation to member countries. However, the existing methodologies have been currently undertaken in this field of study such as the computable general equilibrium (CGE), the global trade analysis project (GTAP) and the standard gravity theory (GT) are both unable and inappropriate to examine this effect in time series data perspective. In this study, the
appropriate and flexible approach with the concept of trade-growth causality time series is conducted to examine the realistically and accurately impact of crises, shocks and policy reform on trade and growth, closer regional economic relations and FTAs for Thailand.

4. FTAs, AFTA AND GRAVITY THEORY

Trade liberalisation is the primary objective of FTAs. Moreover, the welfare improvement and mutual economic growth are also regarded as the other important goals of FTAs. To reach this point, it is needed to assurance the causality effect of trade on economic welfare and growth (Tran Van Hoa, 2004). There are other mutually beneficial outcomes in several non-economic perspectives e.g. closer regional and global cooperation as well as stimulating the competitiveness contributing to more realistically regional and global economic integration.

The trade policy of AFTA was first drafted by the ASEAN Declaration of 8 August 1967. This declaration aimed to stimulate economic growth in the region via trade policy and other various economic cooperation schemes. The progress had been very slow in the early stages. The intensive framework to enhance the ASEAN economic cooperation was developed in the Fourth ASEAN Summit in Singapore in January 1992 through the AFTA. The CEPT schemes for the AFTA was set up in this submit. In November 2004, the Tenth ASEAN Submit was held in Vientiane, Laos. The implementation period of the Vientiane Action Program (VAP) is between 2004 and 2010. The ASEAN Investment Area (AIA) is the important vision of the ASEAN to stimulate investment liberalisation and facilitation. The cooperation policies have been launched to increase the efficient of trade in goods, services and other aspects.

In 2000, Thailand AFTA tariff would slightly exceed 7%, less than half of the applied MFN rate. High tariffs were in the domestic meat and diary, fruit and vegetable, sugar, beverage and tobacco manufacturing industries. Thailand did not apply quantitative restrictions on agriculture food imports; many of the tariff quotas established under the Uruguay Round were not used in practice to restrict imports; instead, lower or zero duties were frequently applied when imports of the products concerned were needed for the domestic processing industries. For the few products whose importation was impeded by high tariffs, partners to the AFTA had unlimited access to market of Thailand as of 2000 at rates not exceeding 20% thereby generating substantial pressure on certain domestic agriculture food sectors. The textiles and clothing industry provided an example of the recent tariff instability in the manufacturing sector, causing unpredictability for importers. Thailand did not protect its textile and clothing industry with import quotas; however, quantitative restrictions and safeguards in export markets substantially restricted its exports (Nagai, 2004).

The useful causality concept of GT using geographical, demographic and other common contributors to explain openness or trade flow liberalisation between partners is considered acceptable appropriate in term of empirical studies in regarding to the expectation that regional trade liberalisation and FTAs enhance trade, growth including economic development and welfare improvement. This theory is widely extended by using other countries in other regions data attempting to explore relationships between trade and other variables such as output fluctuations and income distribution. Based on the case of Thailand and its major partners or blocs included in this study context, the qualitative
review of trade policy to support the implications has also been done. Additionally, the role affected by crises, shocks and policy reform on trade-growth causality for Thailand and its major partners or blocs has not been accommodated or adequately studied in the current literature.

5. A TRADE-GROWTH MODEL TO STUDY THE IMPACT OF SHOCKS AND POLICY REFORM ON THAILAND’S TRADE AND GROWTH

As a novel methodology for our study and also based on related previous studies and the contributions of the study, the impact of openness on trade and growth and the generalised gravity theory (GGT) (see Tran Van Hoa, 2002, 2004a and 2004b) can be linked by two simultaneous implicit functions for trade and growth to be estimated. As a result, the model of Thailand’s openness can be described as follows.

The estimated model that consists generically of 2 equations can be written in mathematically arbitrary form as

Equation 1 Trade-Growth Equation

\[ Y = f(T, CS) \]

Where growth (Y) is defined as GDP, T is defined the as degree of trade participation or density which is measured from the exports plus imports value of goods excluding services, and CS is defined as internal or external crises and shocks or policy reform. Based on this equation, the relationship between openness, trade and growth is examined through the operation of the variable T according to the traditional trade theory. Under this aspect, the specialization and competitiveness of production of goods that possess the comparative advantages leads growth (Appleyard and Field, 1998).

Equation 2 Trade Equation

\[ T = f(Y, X, TH, Z, CS) \]

Where T is defined as the exports plus imports value of goods. X is defined as other economic variables (fiscal, monetary, trade and industry policy) whereas Z is defined as non-economic variable e.g. economic size. Thus, in our study, the conventional trade equation is extended in the case of Thailand by including the other variables that affect Thailand’s trade and growth (TH). These variables are FDI and trade in services. These economic and non-economic variables are associated with the countries’ development and growth (Johansen, 1982; Romer, 1993; Frankel and Romer, 1999; Rose, 2000; Otto et al., 2002; Tran Van Hoa, 2004a and 2004b).

The two-equation model above assumes, essentially that Thailand’s multilateral, regional and bilateral trade (T) with its trading partners cause Thailand’s growth (Y). However, this trade (T) is also affected by its partner’s GDP and other economic and trade-related activities (Cope and Helpman, op. cit.) and internal and external shocks and policy reform in Thailand and in its trading partners (Tran Van Hoa, op. cit.). Therefore, these variables are significant and necessary to include into the model to be estimated. (ch.3)

6. AN EMPIRICAL ESTIMATION OF THE TRADE-GROWTH MODEL INCORPORATING FDI AND SERVICES

The extended relevant model to implement the empirical study on the possible causality impact between Thailand’s openness and growth can be explained by following two-equation simultaneous model can explain its major partners or blocs on growth. This two-equation simultaneous estimated model can be written in stochastic and rate of change (Δ)
forms (see Allen, 1960; Tran Van Hoa, 2004a and 2004b for the proof of the derivation) by the following.

\[ \Delta Y = \chi_1 + \chi_2 \Delta T + \chi_3 \Delta X + \chi_4 \Delta Z + \epsilon_1 \]  
\[ \Delta T = \eta_1 + \eta_2 \Delta Y + \eta_3 \Delta X + \eta_4 \Delta Z + \eta_5 \Delta T + \epsilon_2 \]  

It can be seen that equation (3) and (4) are linear, interdependent. Both circular and instantaneous causality can be observed in these equations.

In order to estimate and implement the model which is equation (3) and (4) to explore the trade and growth causal relationship between Thailand and selected enlarged markets, the geographical elements (distance and area) can be fixed; population can be the proxy for economic size, conventional economic determinants and other associated factors can be used (see Johansen, 1982; Frankel and Rose, 1998; Frankel and Romer, 1999; Rose, 2000; Tran Van Hoa, 2004a and 2004b).

The extended GGT model (that is the GGT model with Thailand’s special structural and development characteristics) is used to examine the impact of trade liberalisation with Thailand’s selected ASEAN and other trading markets in an enlarged ASEAN on Thailand’s growth can be expressed both in the structural equation (5) and the reduced form (6) supported by the followings structural and reduced equations (see Johansen, 1982; Barro and Helpman, 1991; Coe and Helpman, 1993; Romer, 1993; Frankel and Romer, 1999; Rose, 2000; Otto et al., 2002; Tran Van Hoa, 2004a and 2004b).

\[ \Delta Y = \alpha_1 + \alpha_2 \Delta T + \alpha_3 \Delta FDI + \alpha_4 \Delta SER + \alpha_5 \Delta T + \epsilon_1 \]  
\[ \Delta T = \beta_1 + \beta_2 \Delta Y + \beta_3 \Delta FP + \beta_4 \Delta MP + \beta_5 \Delta IN + \beta_6 \Delta TE + \beta_7 \Delta IS + \beta_8 \Delta POP + \beta_9 \Delta CS + \epsilon_2 \]  

From the above, it can be said that Thailand’s trade (T) with its multilateral, regional and selected bilateral FTAs comply with external crises and shocks and foreign direct investment (FDI) and trade in services (SER) cause Thailand’s growth (Y). However, this trade (T) is also affected by its partner’s GDP and other economic and trade-related activities (Cope and Helpman, op. cit.) or internal or external shocks or policy reform in Thailand and in its trading partners (Tran Van Hoa, op. cit.).

As a result, it can be implied from the reduced form of equation (6) that trade of Thailand’s partners is affected by various exogenous factors such as GDP (YT), inflation (IN) – see Romer (1993), fiscal policy (FP), monetary policy (MP), trade policy and exchange rate (TE) – see Rose (2000), industry structure (IS) – see Otto et. al. (2002), population (POP) – see Frankel and Romer (1999) and internal or external shocks or policy reform – see Johansen (1982) and Tran Van Hoa (2004a and 2004b) – of Thailand. CS is defined as the qualitative time-series data dealing with external shocks and policy reforms resulting in the temporally and permanent effects on trade and growth.

The estimated model for intra-ASEAN regional and bilateral trade-growth for Thailand trading partners used in this study can be obtained from the two-simultaneous equations above, equation (5) and (6). Consequently, these equations can be rewritten to estimate and for impact analysis as:

\[ \Delta Y_{TH} = \alpha_1 + \alpha_2 \Delta Y_{AS} + \alpha_3 \Delta FDI_Y + \alpha_4 \Delta SER_Y + \alpha_5 \Delta CS_{88} + \alpha_6 \Delta CS_{97} + \alpha_7 \Delta CS_{02} + \epsilon_1 \]  
\[ \Delta Y_{AS} = \beta_1 + \beta_2 \Delta Y_{TH} + \beta_3 \Delta GB_Y + \beta_4 \Delta MS_Y + \beta_5 \Delta RT + \beta_6 \Delta IN + \beta_7 \Delta EX + \beta_8 \Delta UN + \beta_9 \Delta POP + \beta_{10} \Delta CS_{88} + \beta_{11} \Delta CS_{97} + \beta_{12} \Delta CS_{02} + \epsilon_2 \]  

As a result, it can be said that Thailand’s trade (T) with its multilateral, regional and selected bilateral FTAs comply with external crises and shocks and foreign direct investment (FDI) and trade in services (SER) cause Thailand’s growth (Y). However, this trade (T) is also affected by its partner’s GDP and other economic and trade-related activities (Cope and Helpman, op. cit.) or internal or external shocks or policy reform in Thailand and in its trading partners (Tran Van Hoa, op. cit.).

The estimated model for intra-ASEAN regional and bilateral trade-growth for Thailand trading partners used in this study can be obtained from the two-simultaneous equations above, equation (5) and (6). Consequently, these equations can be rewritten to estimate and for impact analysis as:

\[ \Delta Y_{TH} = \alpha_1 + \alpha_2 \Delta Y_{AS} + \alpha_3 \Delta FDI_Y + \alpha_4 \Delta SER_Y + \alpha_5 \Delta CS_{88} + \alpha_6 \Delta CS_{97} + \alpha_7 \Delta CS_{02} + \epsilon_1 \]  
\[ \Delta Y_{AS} = \beta_1 + \beta_2 \Delta Y_{TH} + \beta_3 \Delta GB_Y + \beta_4 \Delta MS_Y + \beta_5 \Delta RT + \beta_6 \Delta IN + \beta_7 \Delta EX + \beta_8 \Delta UN + \beta_9 \Delta POP + \beta_{10} \Delta CS_{88} + \beta_{11} \Delta CS_{97} + \beta_{12} \Delta CS_{02} + \epsilon_2 \]  

As a result, it can be said that Thailand’s trade (T) with its multilateral, regional and selected bilateral FTAs comply with external crises and shocks and foreign direct investment (FDI) and trade in services (SER) cause Thailand’s growth (Y). However, this trade (T) is also affected by its partner’s GDP and other economic and trade-related activities (Cope and Helpman, op. cit.) or internal or external shocks or policy reform in Thailand and in its trading partners (Tran Van Hoa, op. cit.).
In deriving equations (7) and (8) for 2 trading countries or blocs, it is assumed that country 1’s trade affecting its growth and this trade itself is essentially a demand equation for either imports from country 2 or exports to country 2 or vice versa or both are testable hypotheses. Where in terms of the rates of change, YTH is Thailand’s GDP, TASY is selected ASEAN-4’s (Indonesia, Malaysia, Philippines and Singapore) total trade (imports plus exports) to Thailand divided by Thailand’s GDP, GBY is government budget divided by GDP, YAS is ASEAN-4’s GDP. FDIY is total inward foreign direct investment and SERY is total services. These variables are also divided by Thailand’s GDP. All variables in the model excluding dummy variables are expressed in rates of change form so the measurement units for trading countries’ variables are irrelevant.

The variables GBY, MSY, RT, IN, EX, UN and POP denoted for respectively fiscal and monetary policy, interest rates, inflation, exchange rates, industry policy, Thailand’s population. The ε’s are the disturbances representing other unknown factors but with effects on YTH and TASY respectively (see Frankel and Romer, 1999). CS is a qualitative time-series variable representing internal or external shocks having either temporally or permanently effects on trade and growth with discrete values. The total trade of all these partners divided by Thailand’s GDP is used in the multilateral trade model. The other selected Thailand’s FTAs estimated are consisting of Thailand-USA, Thailand-EU, Thailand-China, Thailand-Japan, Thailand-India and Thailand-Australia. The trade-growth models for these multilateral and selected bilateral trades are constructed similarly.

Most of obtained data is annually and ratio transformation is employed. Trade (imports plus exports), government budget and money supply (M2) are divided by GDP. Unemployment rates are defined as open unemployment divided by labour force. All trade and economic data used in the study are at current prices in dollars. Besides that, three internal and external crises and shocks are determined which including the capital flow liberalisation of 1988 (CS88), the Asia currency and financial crisis of 1997 (CS97) and the financial institutions policy reforms of 2002 (CS02).

The empirical finding implications of the above model can be used to study the relationship or transmission mechanism including the linkages between Thailand’s growth and trade with its major trading partners. Besides that, this empirically supported relationship can be regarded as the evidence to propose the enhancement of trade, services and investment from trade liberalisation for Thailand in the context of regional and bilateral FTAs. The implications for Thailand’s trade and closer economic relation policy are also proposed based on the empirical findings.

7. AN ECONOMETRIC FINDINGS ON THAILAND’S TRADE WITH ITS MAJOR PARTNERS AND THAILAND’S GROWTH

This part describes the final and preferred empirical findings for 8 models including total, regional and bilateral trade-growth models and base on equations (7) and (8) in the previous chapter for Thailand and its seven major trading partners and blocs are given in the following tables. These bilateral FTAs or trading blocs consist of Thailand-ASEAN (4), Thailand-USA FTA, Thailand-EU proposed FTA, Thailand-China FTA, Thailand-Japan FTA, Thailand-India FTA and Thailand-Australia FTA. Because of the importance of the estimation methods employed that lead to different results despite the same model and data used in the process. Consequently, two techniques have been used to for each model based on the aim of statistical efficiency comparison. These are consisting of the OLS and 2SLS
an IV) as well as the cases of without FDI and services, with FDI and with both FDI and services respectively. The 2SLS (an IV) is used to obtain the better results for the comparison perspective.

This section also reveals the estimation results of regional and bilateral trade models. The openness variable in regional trade model is defined as total trade between Thailand and ASEAN-4 (Indonesia, Malaysia, the Philippines and Singapore) trading partners divided by Thailand’s GDP. For the openness variable in the bilateral models, it is defined as total trade between Thailand and its selected trading partners.

Sources of data: World Development Indicators Database, World Bank (2004) and ICSEAD Database (2004)

From the results given in Table 1, it can be noted the important following findings. First, while having high success in modelling output growth as defined by change in GDP is difficult, the estimated model of Thai growth via each trading partners has considerably high modelling performance that is R² reaching up to almost and more than 60 per cent in
almost estimated models and especially more than 70 per cent for Thailand and Japan model. Second, when considering the dynamic features of this estimated model using graph plots and Durbin-Watson statistics, it can be observed that there is no serious first or higher autocorrelation attitude. Third, openness as defined by total trade/GDP in case between Thailand and Japan has positive and significant impact. For other models, the openness has positive but insignificant impact except Thailand and Australia model has negative but insignificant impact. In the case of Thailand and India model, the openness is positive in OLS and negative in 2SLS but insignificant impact. FDI has both positive and negative but insignificant impact in all estimated models. Similarly, services are negative but insignificant in all estimated models. Finally, the combination of three crises and shocks into the model reveals the different results. The financial crisis of 1997 has the obviously negative and significant impact whereas the capital liberalisation and financial institutions and system reforms policies have considerably positive and significant impact on the economic performance of Thailand in the estimated period in all models.

The modelling performance is highest for the Thailand-Japan and Thailand-China respectively in terms of $R^2$, adjusted $R^2$, sum squares of errors and the Durbin-Watson statistics. The Durbin-Watson statistics is high enough to conclude that the serious first or higher autocorrelation induce does not exist in all estimated models. Second, the estimation result of independent variables is different in each model. As a result, it can be described by the followings. It is found that openness is positive and significant impact in the case of total trade model and bilateral trade model of Thailand-Japan FTA. In regards to the FDI and services are both positive and negative but insignificant in all estimated models. Finally, it can be seen that crises and shocks contribute the different impact on the economic performance of Thailand during the period of study in all models. The Asian financial crisis of 1997 is apparently and considerably negative and significant impact as the origin of contagion effects in the region. On the other hand, the capital flow liberalisation of 1988 and the financial institutions and system reform policies of 2002 are obviously positive and significant on the economic performance and recovery of Thailand in the entire estimated period.

8. THE MODELLING RELIABILITY

The explanation of modelling reliability is included in this section. To complete this task for trade-growth model in a simultaneous-equation context, it needs to calculate the reliable proxy for T from its reduced form for each of the estimations. The standard evaluation criteria including the correlation coefficient, the root mean square errors (RMSE) and the Theil Inequality Coefficient decompositions, namely $U_m$ (bias), $U_s$ (variance), and $U_c$ (covariance) are calculated to evaluate the proxy performance of T comparing to its actual T in each estimated GGT model.

Notes: Um+Us+Uc=1 (See Pindyck and Robinfeld, 1998). The estimates are based on E-views calculation.

From the Table 2, it can be said that the proxy for T is very good estimated to T in all models excluding Thailand-India and Thailand-USA models. The correlation coefficients of all models except these two models are apparently higher than 70 per cent up to nearly 90 per cent for Thailand-Japan model. The calculated RMSE, mean error and the bias, variance and covariance are gradual except for the Thailand-India and Thailand-USA models. Consequently, these empirical findings can be used to support the robustness and reliability of estimation results by the OLS and 2SLS (IV). Furthermore, these empirical results can also be used as the guidelines to propose the credible policy implications and recommendations in the proceeding section.

The next step to complete the estimation results interpretation is to compare the actual trade flows and their estimates from the estimated GGT models. The results of this procedure can be shown and explained by the following charts.
The charts of actual and trade flows and selected trading partners and their estimates from estimated GGT models can be plotted by chart 1 to 8. It can be seen that the using of new modelling flexible approach of simultaneous-equation and functional free GGT approach, the estimated proxy for T apparently imitates all troughs, peaks and turning points of the actual T in nearly all models especially bilateral trade models between Thailand and Australia, Thailand and China, Thailand and Japan. The other important aspect of this property is expressed in term of rates of changes of changes of economic variables leads to its modelling success.

9. THE INTERPRETATION OF THE MAIN ESTIMATION RESULTS

The first interpretation of main estimation results is reported in this section. The economic interpretation regards to the main estimation results in the previous part can be discussed by the followings. The structure GGT models used for Thailand’s openness model in this study consisting of both the main and conventional components of the determinants and relationship between trade and growth. Consequently, these major components and relationship can be examined for the 8 countries and blocs under this research. In regard to comparative aspect, the estimation results of GGT models are fairly compatible with other similar previous studies of different methods of trade-growth studies such as the CGE, the GT or other quantitative trade-growth studies. The empirical findings on trade-growth correlation that trade has been broadened by incorporating services and investment as well as the impact of crises, shocks and policy reform explained in the last section contribute to several new and interesting economic interpretation.

The findings can also be seen as the empirical support or rejection of these current trade liberalisation policy negotiation and implementation initiatives of Thailand under the multilateral, regional and bilateral contexts. Moreover, these findings can be attributed to the important, credible and practical implications and recommendations for creating FTA and related economic cooperation dialogues according to the keen interesting of Thailand.
With regarding to empirical results show that trade with its global trading partners as defined by the relative openness size to its GDP, only in the specific case of multilateral and bilateral with Japan have a gradual support in term of statistically significant and Thailand’s growth beneficial determinants. Besides that, according to the empirical findings, Thailand gains most from its bilateral trade with Japan. This result can be strongly supported by the fact that trade value and volume with Japan is the highest comparing to other trade partners in this study. This claim can be linked to the priority setting consideration of trade and economic cooperation for policy makers in Thailand to gain the mutual benefits from Thailand-Japan FTA. In addition, it can be said that trade is the essential key drivers for the Thai economy in current decades (NESDB, 2005).

More specifically, it can be said that trade liberalisation benefits Thailand most in term of bilateral Thailand-Japan FTA. The positive and significant impact of openness can be explained by the generalised gravity theory due to the geographical distance, location and transportation cost advantage and economic size of Japan. As a result, the negotiation and implementation of Thailand-Japan FTA including other trade related and economic cooperation issues should be set in the top priority.

The combination of trade in goods, services and investment is the dominant feature of this study. Services and investment are measured by credit services account of balance of payment and total inward FDI. Both services and investment have negative but insignificant impact. These findings can be attributed to the volatility and small proportion of GDP during the estimation period and inward FDI is mainly to the manufacturing sector. So, the impact of inward FDI on GDP manufactured can be observed more clearly than on total GDP. Nevertheless, not only trade in goods but also trade in services and investment can be regarded as the important elements of nearly all current FTA negotiations coverage to enhance the economic performance of Thailand and other partners of the FTAs. Additionally, the effort to include the framework of competition law and policy to accelerate trade in services and investment has strongly undertaken in almost all recent FTAs (Tran Van Hoa, 2004).

The other important feature of estimated GGT models in this study is the specification and combination of shocks, crises and policy reform variables. These variables contain sudden or gradual with short-term and long-term effects. It can not be observed this feature in other related methods and models e.g. the CGE, the GTAP and the GT. These shocks and policy reform are major recent economic developments in Thailand. First is the capital liberalisation of 1988 via the implementation of the BIBF scheme resulting in freer borrowing from aboard mainly by financial institutions. Second is the Asia financial crisis of 1997 commenced in Thailand in July 1997 resulting in the floating of Thai baht and contagion effect spread out to other countries in the region. Third is the financial institutions and system reform of 2002. This policy reform was implemented to strengthen the fragile financial institutions and system of Thailand and to protect the crisis reoccurrence.

According to the empirical findings, it shows that the capital liberalisation of 1988 can be considered as essential and significant benefits policy reform for economic performance of Thailand in nearly all GGT models. This can be explained that Thailand received extremely huge portfolio investment inflows and bank loans in the late 1980s because of large interest rate between onshore and offshore markets resulting in the expansion of credit and investment. Contrastly, the Asia financial crisis of 1997 had obvious massive damage
impact on economic performance of Thailand in all GGT models. For the financial institutions and system reform, the empirical outcomes are remarkable. This policy reform has obvious positive and significant impact on Thailand’s economic performance. This finding can be contributed to establish of the Thai Asset Management Corporation (TAMC) to manage, restructuring and solve the debts particularly NPLs. As a result, the external debts declined to 36 per cent in 2003 (ICSEAD, 2003). Besides that, the balance of payment also turnarounds to favourable trends after the crisis. These factors contribute to the recovery of Thailand’s economy.

10. THE IMPLICATIONS FOR THAILAND’S TRADE AND CLOSER ECONOMIC RELATION POLICY

The implications for Thailand’s trade and closer economics relation policy are proposed in this section. To summary, the fiscal and monetary including industrial policies have to be supported each other as well as the acceleration of trade liberalisation need to be implemented simultaneously. Slow and inefficient budget distribution is the obstacle to stimulate the domestic consumption demand and investment. The performance based and rolling budgeting is the alternative to increase the efficiency of Thailand’s budget system (Puntasen, 2003). The other vital aspect of fiscal policy implication is to increase long-run domestic purchasing power by tax policy. Besides that, the mega projects investment acceleration is necessary to enhance economic recovery and growth.

Taking account to the monetary policy, the recent inflation targeting policy has to be implemented more efficiency to controlling the inflation rate and exchange rate fluctuation (ADB, 2000). During the crisis period, both the inflation and exchange rate rise remarkably. Nevertheless, these macroeconomic indicators become relatively stable in the early 2000s. The baht is excessive overvalued in the late 2006 comparing to neighbours in Asia. The Bank of Thailand adopts the required reserve margin for foreign capital investment fund to protect the baht from over speculation and controlling the exchange rate stability. The full implementation of this scheme is abandoned in early 2008 mainly because of the more sufficient stable of capital flow balance. Several strategies are undertaken to promote the industrialisation essentially the manufactured export sector. The tax regulation relaxing is the direct incentive to attract long-run FDI. The establishment of export-processing zones and research and development support are the indirect incentives.

Trade liberalisation is also an essential engine of growth for developing countries. Thailand has to implement trade liberalisation according the multilateral, regional and unilateral contexts. Thailand has to collectively and mutually more intensive cooperation with other developing countries to raise bargaining power to reap the more benefits and guaranteeing the fair regulations of the next negotiations in terms of the new issues such as services, investment, intellectual property rights, competition policy, anti-dumping and countervailing duties and labour and environment standards. Thailand is an obvious active in the CEPT implementation. Nevertheless, this process is remaining in progress due to the economic development gap between old and new members including the difficulty in total tariff and non-tariff barriers despite many facilitation schemes are set up. Presently, the AFTA has extended the wider and deeper economic cooperation to achieve the AEAN Investment Area and single market in 2020.

In regard to the unilateral trade liberalisation, the inward-oriented policy has been replaced by intensive export-oriented policy in 1980s due to the ineffectiveness of the former during
the last two decades (Akrasanee et al., 1991). The high tariff rates in most import
categories are decreased massively especially the raw materials and intermediate products
including the semi-manufactured products using the finish manufactured products
production. The non-tariffs barriers subjected to both imports and exports are also more
alleviated.

The domestic policy reforms are mainly motivated by the urgent crisis solution requirement.
To recovery the economy, the financial institution and system is the top priority sector
needed to restore. The FIDF and TAMC have been built up to solve the serve NPLs
problem of this sector via debt restructuring. Most of other neighbours in Southeast Asia
request the assistance packages from the IMF including Thailand due to the rapidly
contagion effect.
